- How to use FOS-V3
  - First time run
  - Build and run FOS
  - Debugging kernel
  - Debugging user executables

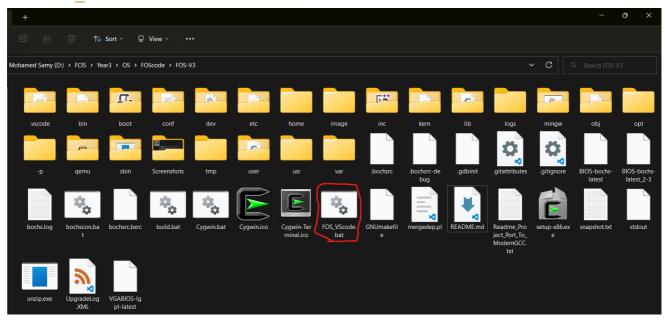

## How to use FOS-V3

## First time run

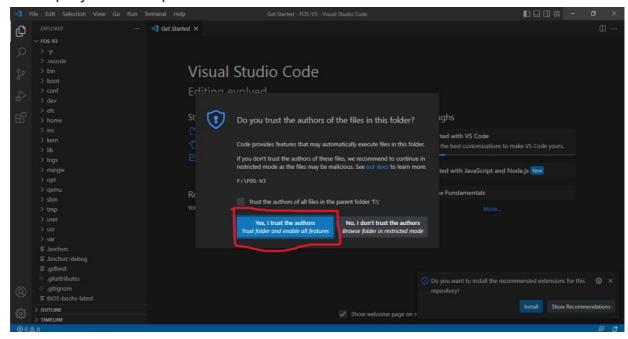

- Download the FOS-V3 rar file from Here
- Extract FOS-V3 in a new folder:

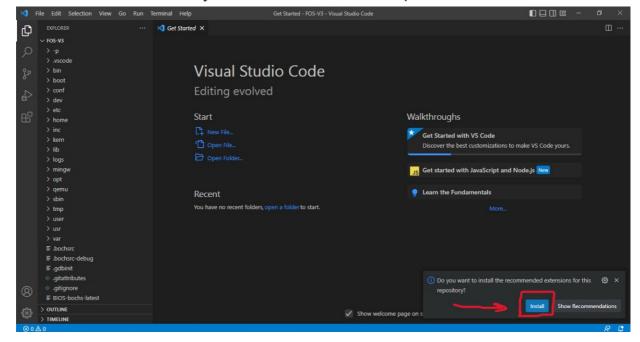

• Run FOS VScode.bat

- VS Code should now open in the project folder
  - Trust project workspace

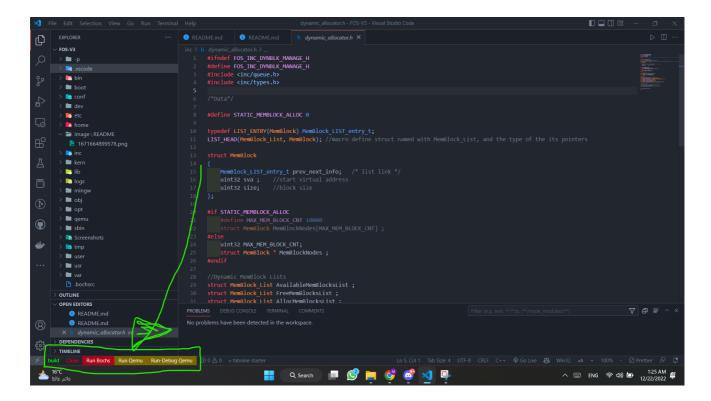

You will be automatically notified to download required extensions, Click Yes

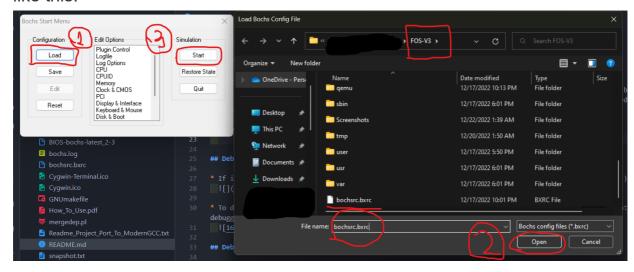

#### **Build and run FOS**

 After extensiions install four buttons will appear to build, clean and run FOS on both emulators

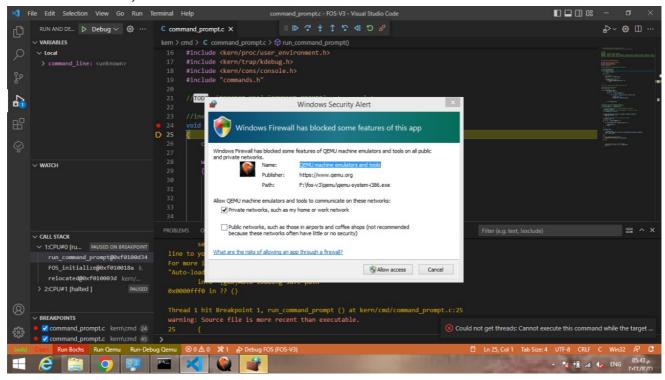

- Build just builds the FOS image, but Run will also build FOS again every time
   (This behavior will be modified later), also note that build can fail on the first time
   after installation or after Clean as it creates the required directories (this will also
   be improved later)
- Run Bochs and Run Qemu Will run FOS in eash Emulator respectively
  - Note: when running on bochs you may need to specify the configuration file like this:

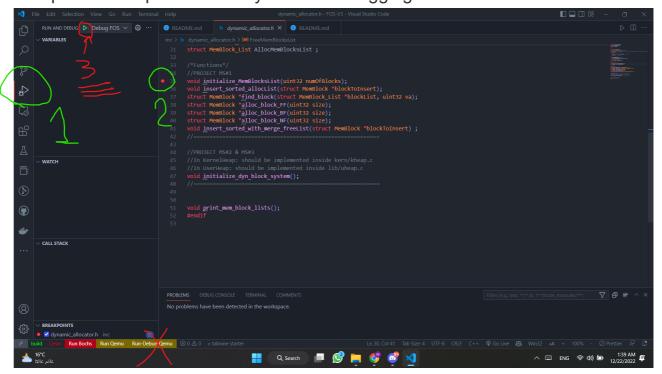

This behavior was intended during testing and will be removed later

## **Debugging kernel**

 If it's the first time to run the debugger, you may see somthing like this (Just click Allow access):

 To debug Use The Green Button on Debug page and make sure that you put all the required breakpoints before you start debugging.

# Debugging user executables

 The default configuration debugs the Kernel binary, to debug a user program go to .vscode\launch.json

 Create a copy of the current configuration and put it into the configurations array (separated by commas), and set the name of your new configuration the change the executable path to obj/user/"The name of user program you want to debug", Note: the name of user program binary is usually the same name of the code file but without extension Ex: fos add.c -> fos add

```

        > 📭 conf
       > 🖿 dev
                                                               "preLaunchTask": "build-debug",
        > 🌅 etc
       ∨ 🗃 image\README
                                                               "type": "gdb",
"request": "attach",
          2 1671664899578.png
          1671665163412.png
                                                               "name": "Debug User fos_add", // Set the name of the debug configuration
                                                              "remote": true,
"target": ":26000",
          1671666529848.png
        > 📴 inc
                                                               "cwd": "${workspaceRoot}",
        > 🖿 kern
                                                               "preLaunchTask": "build-debug",
         📭 lib
        > i mingw
        > 🖿 obj
        > 🖿 opt
```

 Now add breakpoints to the user program code and select its debug configuration you just created from the list

• Click the **Green Button** and start debugging as usual
